Docket No. AUS9-2000-0414-US1

As the speed of computers continues to increase, the amount of heat generated by the circuits within the computers continues to increase. For many circuits and applications, increased heat degrades the performance of the computer. These circuits need to be cooled in order to perform most efficiently. In many low end computers, such as personal computers, the computer may be cooled merely by using a fan and fins for convective cooling. However, for larger computers, such as main frames, that perform at faster speeds and generate much more heat, these solutions are not viable.

Currently, many main frames utilize vapor compression coolers to cool the computer. These vapor compression coolers perform essentially the same as the central air conditioning units used in many homes. However, vapor compression coolers are quite mechanically complicated requiring insulation and hoses that must run to various parts of the main frame in order to cool the particular areas that are most susceptible to decreased performance due to overheating.

A much simpler and cheaper type of cooler are thermoelectric coolers. Thermoelectric coolers utilize a physical principle known as the Peltier Effect, by which DC current from a power source is applied across two dissimilar materials causing heat to be absorbed at the junction of the two dissimilar materials. Thus, the heat is removed from a hot substance and may be transported to a heat sink to be dissipated, thereby cooling the hot substance. Thermoelectric coolers may be fabricated within an integrated circuit chip and may cool specific hot spots directly without the need for complicated

Docket No. AUS9-2000-0414-US1

mechanical systems as is required by vapor compression coolers.

However, current thermoelectric coolers are not as efficient as vapor compression coolers requiring more power to be expended to achieve the same amount of cooling. Furthermore, current thermoelectric coolers are not capable of cooling substances as greatly as vapor compression coolers. Therefore, a thermoelectric cooler with improved efficiency and cooling capacity would be desirable so that complicated vapor compression coolers could be eliminated from small refrigeration applications, such as, for example, main frame computers, thermal management of hot chips, RF communication circuits, magnetic read/write heads, optical and laser devices, and automobile refrigeration systems.

Docket No. AUS9-2000-0414-US1

### SUMMARY OF THE INVENTION

5        The present invention provides a thermoelectric device with improved efficiency. In one embodiment, the thermoelectric device includes a first thermoelement and a second thermoelement electrically coupled to the first thermoelement. An array of first tips are in close  
10 physical proximity to, but not necessarily in physical contact with, the first thermoelement at a first set of discrete points. An array of second tips are in close physical proximity to, but not necessarily in physical contact with, the second thermoelement at a second set of  
15 discrete points. The first and second conical are constructed entirely from metal, thus reducing parasitic resistances.

Docket No. AUS9-2000-0414-US1

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

With reference now to the figures and, in particular, with reference to **Figure 1**, a high-level block diagram of a Thermoelectric Cooling (TEC) device is depicted in accordance with the prior art. Thermoelectric cooling, a well known principle, is based on the Peltier Effect, by which DC current from power source **102** is applied across two dissimilar materials causing heat to be absorbed at the junction of the two dissimilar materials. A typical thermoelectric cooling device utilizes p-type semiconductor **104** and n-type semiconductor **106** sandwiched between poor electrical conductors **108** that have good heat conducting properties. N-type semiconductor **106** has an excess of electrons, while p-type semiconductor **104** has a deficit of electrons.

As electrons move from electrical conductor **110** to n-type semiconductor **106**, the energy state of the electrons is raised due to heat energy absorbed from heat source **112**. This process has the effect of transferring heat energy from heat source **112** via electron flow through n-type semiconductor **106** and electrical conductor **114** to heat sink **116**. The electrons drop to a lower energy state and release the heat energy in electrical conductor **114**.

The coefficient of performance,  $\eta$ , of a cooling refrigerator, such as thermoelectric cooler **100**, is the ratio of the cooling capacity of the refrigerator divided

Docket No. AUS9-2000-0414-US1

by the total power consumption of the refrigerator. Thus the coefficient of performance is given by the equation:

$$\eta = \frac{\alpha T_c - \frac{1}{2} I^2 R - K \Delta T}{I^2 R + \alpha \Delta T}$$

5

where the term  $\alpha I T_c$  is due to the thermoelectric cooling, the term  $\frac{1}{2} I^2 R$  is due to Joule heating backflow, the term  $K \Delta T$  is due to thermal conduction, the term  $I^2 R$  is due to Joule loss, the term  $\alpha I \Delta T$  is due to work done against the Peltier voltage,  $\alpha$  is the Seebeck coefficient for the material,  $T_c$  is the temperature of the heat source, and  $\Delta T$  is the difference in the temperature of the heat source from the temperature of the heat sink.

The maximum coefficient of performance is derived by optimizing the current,  $I$ , and is given by the following relation:

15

$$\eta_{\max} = \left( \frac{T_c}{\Delta T} \right) \left[ \frac{\gamma - T_h/T_c}{\gamma + 1} \right]$$

20 where

$$\gamma = \sqrt{1 + \frac{\alpha^2 \sigma}{\lambda} \left( \frac{T_h + T_c}{2} \right)}$$

and

Docket No. AUS9-2000-0414-US1

$$\varepsilon = \frac{\gamma - T_h/T_c}{\gamma + 1}$$

where  $\varepsilon$  is the efficiency factor of the refrigerator.  
The figure of merit,  $ZT$ , is given by the equation:

5

$$ZT = \frac{\alpha^2 \sigma T}{\lambda}$$

where  $\lambda$  is composed of two components:  $\lambda_e$ , the component due to electrons, and  $\lambda_L$ , the component due to the  
10 lattice. Therefore, the maximum efficiency,  $\varepsilon$ , is achieved as the figure of merit,  $ZT$ , approaches infinity. The efficiency of vapor compressor refrigerators is approximately 0.3. The efficiency of conventional thermoelectric coolers, such as thermoelectric cooler 100  
15 in **Figure 1**, is typically less than 0.1. Therefore, to increase the efficiency of thermoelectric coolers to such a range as to compete with vapor compression refrigerators, the figure of merit,  $ZT$ , must be increased to greater than 2. If a value for the figure of merit,  
20  $ZT$ , of greater than 2 can be achieved, then the thermoelectric coolers may be staged to achieve the same efficiency and cooling capacity as vapor compression refrigerators.

With reference to **Figure 2**, a cross sectional view

Docket No. AUS9-2000-0414-US1

of a thermoelectric cooler with enhanced structured interfaces is depicted in accordance with the present invention. Thermoelectric cooler 200 includes a heat source 226 from which, with current  $I$  flowing as  
5 indicated, heat is extracted and delivered to heat sink 202. Heat source 226 may be thermally coupled to a substance that is desired to be cooled. Heat sink 202 may be thermally coupled to devices such as, for example, a heat pipe, fins, and/or a condensation unit to  
10 dissipate the heat removed from heat source 226 and/or further cool heat source 226.

Heat source 226 is comprised of p- type doped silicon. Heat source 226 is thermally coupled to n+ type doped silicon regions 224 and 222 of tips 250. N+ type  
15 regions 224 and 222 are electrical conducting as well as being good thermal conductors. Each of N+ type regions 224 and 222 forms a reverse diode with heat source 226 such that no current flows between heat source 226 and n+ regions 224 and 222, thus providing the electrical  
20 isolation of heat source 226 from electrical conductors 218 and 220.

Heat sink 202 is comprised of p- type doped silicon. Heat sink 202 is thermally coupled to n+ type doped silicon regions 204 and 206. N+ type regions 204 and 206  
25 are electrically conducting and good thermal conductors. Each of N+ type regions 204 and 206 and heat sink 202 forms a reverse diode so that no current flows between the N+ type regions 204 and 206 and heat sink 202, thus providing the electrical isolation of heat sink 202 from  
30 electrical conductor 208. More information about

Docket No. AUS9-2000-0414-US1

electrical isolation of thermoelectric coolers may be found in commonly U.S. Patent Application Serial No. 09/458,270 entitled "Electrically Isolated Ultra-Thin Substrates for Thermoelectric Coolers" ~~(IBM Docket No. AUS9-99-0413-US1)~~ <sup>now U.S. Patent 6,222,113</sup> assigned to the International Business Machines Corporation of Armonk, New York and filed on December 9, 1999, the contents of which are hereby incorporated herein for all purposes.

The need for forming reverse diodes with n+ and p- regions to electrically isolate conductor 208 from heat sink 202 and conductors 218 and 220 from heat source 226 is not needed if the heat sink 202 and heat source 226 are constructed entirely from undoped non-electrically conducting silicon. However, it is very difficult to ensure that the silicon is entirely undoped. Therefore, the presence of the reverse diodes provided by the n+ and p- regions ensures that heat sink 202 and heat source 226 are electrically isolated from conductors 208, 218, and 220. Also, it should be noted that the same electrical isolation using reverse diodes may be created other ways, for example, by using p+ type doped silicon and n- type doped silicon rather than the p- and n+ types depicted. The terms n+ and p+, as used herein, refer to highly n doped and highly p doped semiconducting material respectively. The terms n- and p-, as used herein, mean lightly n doped and lightly p doped semiconducting material respectively.

Thermoelectric cooler 200 is similar in construction to thermoelectric cooler 100 in **Figure 1**. However, N-type 106 and P-type 104 semiconductor structural interfaces have been replaced with superlattice

Docket No. AUS9-2000-0414-US1

thermoelement structures 210 and 212 that are electrically coupled by electrical conductor 208.

Electrical conductor 208 may be formed from platinum (Pt) or, alternatively, from other conducting materials, such as, for example, tungsten (W), nickel (Ni), or titanium copper nickel (Ti/Cu/Ni) metal films.

A superlattice is a structure consisting of alternating layers of two different semiconductor materials, each several nanometers thick. Thermoelement 210 is constructed from alternating layers of N-type semiconducting materials and the superlattice of thermoelement 212 is constructed from alternating layers of P-type semiconducting materials. Each of the layers of alternating materials in each of thermoelements 210 and 212 is 10 nanometers (nm) thick. A superlattice of two semiconducting materials has lower thermal conductivity,  $\lambda$ , and the same electrical conductivity,  $\sigma$ , as an alloy comprising the same two semiconducting materials.

In one embodiment, superlattice thermoelement 212 comprises alternating layers of p-type bismuth chalcogenide materials such as, for example, alternating layers of  $\text{Bi}_2\text{Te}_3/\text{Sb}_2\text{Te}_3$  with layers of  $\text{Bi}_{0.5}\text{Sb}_{1.5}\text{Te}_3$ , and the superlattice of thermoelement 210 comprises alternating layers of n-type bismuth chalcogenide materials, such as, for example, alternating layers of  $\text{Bi}_2\text{Te}_3$  with layers of  $\text{Bi}_2\text{Se}_3$ . Other types of semiconducting materials may be used for superlattices for thermoelements 210 and 212 as well. For example, rather than bismuth chalcogenide materials, the superlattices of thermoelements 210 and

Docket No. AUS9-2000-0414-US1

212 may be constructed from cobalt antimony skutteridite materials.

Thermoelectric cooler 200 also includes tips 250 through which electrical current  $I$  passes into  
5 thermoelement 212 and then from thermoelement 210 into conductor 218. Tips 250 includes  $n^+$  type semiconductor 222 and 224 formed into pointed conical structures with a thin overcoat layer 218 and 220 of conducting material, such as, for example, platinum (Pt). Other conducting  
10 materials that may be used in place of platinum include, for example, tungsten (W), nickel (Ni), and titanium copper nickel (Ti/Cu/Ni) metal films. The areas between and around the tips 250 and thermoelectric materials 210 and 212 should be evacuated or hermetically sealed with a  
15 gas such as, for example, dry nitrogen.

On the ends of tips 250 covering the conducting layers 218 and 220 is a thin layer of semiconducting material 214 and 216. Layer 214 is formed from a P-type material having the same Seebeck coefficient,  $\alpha$ , as the  
20 nearest layer of the superlattice of thermoelement 212 to tips 250. Layer 216 is formed from an N-type material having the same Seebeck coefficient,  $\alpha$ , as the nearest layer of thermoelement 210 to tips 250. The P-type thermoelectric overcoat layer 214 is necessary for  
25 thermoelectric cooler 200 to function since cooling occurs in the region near the metal where the electrons and holes are generated. The n-type thermoelectric overcoat layer 216 is beneficial, because maximum cooling occurs where the gradient (change) of the Seebeck  
30 coefficient is maximum. The thermoelectric overcoat 214

Docket No. AUS9-2000-0414-US1

for the P-type region is approximately 60 nm thick. A specific thickness of the n-type thermoelectric overcoat 216 has yet to be fully refined, but it is anticipated that it should be in a similar thickness range to the  
5 thickness of the thermoelectric overcoat 214.

By making the electrical conductors, such as, conductors 110 in Figure 1, into pointed tips 250 rather than a planer interface, an increase in cooling efficiency is achieved. Lattice thermal conductivity,  $\lambda$ ,  
10 at the point of tips 250 is very small because of lattice mismatch. For example, the thermal conductivity,  $\lambda$ , of bismuth chalcogenides is normally approximately 1 Watt/meter\*Kelvin. However, in pointed tip structures, such as tips 250, the thermal conductivity is reduced,  
15 due to lattice mismatch at the point, to approximately 0.2 Watts/meter\*Kelvin. However, the electrical conductivity of the thermoelectric materials remains relatively unchanged. Therefore, the figure of merit,  $ZT$ , may increased to greater than 2.5 for this kind of  
20 material. Another type of material that is possible for the superlattices of thermoelements 210 and 212 is cobalt antimony skutteridites. These type of materials typically have a very high thermal conductivity,  $\lambda$ , making them normally undesirable. However, by using the  
25 pointed tips 250, the thermal conductivity can be reduced to a minimum and produce a figure of merit,  $ZT$ , for these materials of greater than 4, thus making these materials very attractive for use in thermoelements 210 and 212. Therefore, the use of pointed tips 250 further increases  
30 the efficiency of the thermoelectric cooler 200 such that

Docket No. AUS9-2000-0414-US1

it is comparable to vapor compression refrigerators.

Another advantage of the cold point structure is that the electrons are confined to dimensions smaller than the wavelength (corresponding to their kinetic energy). This type of confinement increases the local density of states available for transport and effectively increases the Seebeck coefficient. Thus, by increasing  $\alpha$  and decreasing  $\lambda$ , the figure of merit  $ZT$  is increased.

Normal cooling capacity of conventional thermoelectric coolers, such as illustrated in Figure 1, are capable of producing a temperature differential,  $\Delta T$ , between the heat source and the heat sink of around 60 Kelvin. However, thermoelectric cooler 200 is capable of producing a temperature differential on the order of 150 Kelvin. Thus, with two thermoelectric coolers coupled to each other, cooling to temperatures in the range of liquid Nitrogen (less than 100 Kelvin) is possible. However, different materials may need to be used for thermoelements 210 and 212. For example, bismuth telluride has a very low  $\alpha$  at low temperature (i.e. less than -100 degrees Celsius). However, bismuth antimony alloys perform well at low temperature.

Another advantage of the cobalt antimony skutteridite materials over the bismuth chalcogenide materials, not related to temperature, is the fact the cobalt antimony skutteridite materials are structurally more stable whereas the bismuth chalcogenide materials are structurally weak.

Those of ordinary skill in the art will appreciate that the construction of the thermoelectric cooler in

Docket No. AUS9-2000-0414-US1

**Figure 2** may vary depending on the implementation. For example, more or fewer rows of tips **250** may be included than depicted in **Figure 1**. The depicted example is not meant to imply architectural limitations with respect to  
5 the present invention.

With reference now to **Figure 3**, a planer view of thermoelectric cooler **200** in **Figure 2** is depicted in accordance with the present invention. Thermoelectric cooler **300** includes an n-type thermoelectric material  
10 section **302** and a p-type thermoelectric material section **304**. Both n-type section **302** and p-type section **304** include a thin layer of conductive material **306** that covers a silicon body.

Section **302** includes an array of conical tips **310**  
15 each covered with a thin layer of n-type material **308** of the same type as the nearest layer of the superlattice for thermoelement **210**. Section **304** includes an array of conical tips **312** each covered with a thin layer of p-type material **314** of the same type as the nearest layer of the  
20 superlattice for thermoelement **212**.

With reference now to **Figures 4A** and **4B**, a cross sectional views of tips that may be implemented as one of tips **250** in **Figure 2** is depicted in accordance with the present invention. Tip **400** includes a silicon cone that  
25 has been formed with a cone angle of approximately 35 degrees. A thin layer **404** of conducting material, such as platinum (Pt), overcoats the silicon **402**. A thin layer of thermoelectric material **406** covers the very end of the tip **400**. The cone angle after all layers have  
30 been deposited is approximately 45 degrees. The

Docket No. AUS9-2000-0414-US1

effective tip radius of tip 400 is approximately 50 nanometers.

Tip 408 is an alternative embodiment of a tip, such as one of tips 250. Tip 408 includes a silicon cone 414 with a conductive layer 412 and thermoelectric material layer 410 over the point. However, tip 408 has a much sharper cone angle than tip 400. The effective tip radius of tip 408 is approximately 10 nanometers. It is not known at this time whether a broader or narrower cone angle for the tip is preferable. In the present embodiment, conical angles of 45 degrees for the tip, as depicted in Figure 4A, have been chosen, since such angle is in the middle of possible ranges of cone angle and because such formation is easily formed with silicon with a platinum overcoat. This is because a KOH etch along the 100 plane of silicon naturally forms a cone angle of 54 degrees. Thus, after the conductive and thermoelectric overcoats have been added, the cone angle is approximately 45 degrees.

With reference now to Figure 5, a cross sectional view illustrating the temperature field of a tip near to a superlattice is depicted in accordance with the present invention. Tip 504 may be implemented as one of tips 250 in Figure 2. Tip 504 has a effective tip radius,  $a$ , of 30-50 nanometers. Thus, the temperature field is localized to a very small distance,  $r$ , approximately equal to  $2a$  or around 60-100 nanometers. Therefore, a superlattice 502 need to be only a few layers thick with a thickness,  $d$ , of around 100 nanometers. Therefore, using pointed tips, a thermoelectric cooler with only 5-10 layers for the superlattice is sufficient.

Docket No. AUS9-2000-0414-US1

Thus, fabricating a thermoelectric cooler, such as, for example, thermoelectric cooler 200, is not extremely time consuming, since only a few layers of the superlattice must be formed rather than numerous layers which can be very time consuming. Thus, thermoelectric cooler 200 can be fabricated very thin (on the order of 100 nanometers thick) as contrasted to prior art thermoelectric coolers which were on the order of 3 millimeters or greater in thickness.

Other advantages of a thermoelectric cooler with pointed tip interfaces in accordance with the present invention include minimization of the thermal conductivity of the thermoelements, such as thermoelements 210 and 212 in Figure 2, at the tip interfaces. Also, the temperature/potential drops are localized to an area near the tips, effectively achieving scaling to sub-100-nanometer lengths. Furthermore, using pointed tips minimizes the number layers for superlattice growth by effectively reducing the thermoelement lengths. The present invention also permits electrodeposition of thin film structures and avoids flip-chip bonds. The smaller dimensions allow for monolithic integration of n-type and p-type thermoelements.

The thermoelectric cooler of the present invention may be utilized to cool items, such as, for example, specific spots within a main frame computer, lasers, optic electronics, photodetectors, and PCR in genetics.

With reference now to Figure 6, a cross sectional view of a thermoelectric cooler with enhanced structured interfaces with all metal tips is depicted in accordance with the present invention. Although the present

Docket No. AUS9-2000-0414-US1

invention has been described above as having tips 250 constructed from silicon cones constructed from the n+ semiconducting regions 224 and 222, tips 250 in **Figure 2** may be replaced by tips 650 as depicted in **Figure 6**.

5 Tips 650 have all metal cones 618 and 620. In the depicted embodiment, cones 618 and 620 are constructed from copper and have a nickel overcoat layer 660 and 662. Thermoelectric cooler 600 is identical to thermoelectric cooler 200 in all other respects, including having a  
10 thermoelectric overcoat 216 and 214 over the tips 650. Thermoelectric cooler 600 also provides the same benefits as thermoelectric cooler 200. However, by using all metal cones rather than silicon cones covered with conducting material, the parasitic resistances within the  
15 cones become very low, thus further increasing the efficiency of thermoelectric cooler 600 over the already increased efficiency of thermoelectric cooler 200. The areas surrounding tips 650 and between tips 650 and thermoelectric materials 210 and 212 should be vacuum or  
20 hermetically sealed with a gas, such as, for example, dry nitrogen.

Also, as in **Figure 2**, heat source 226 is comprised of p- type doped silicon. In contrast to **Figure 2**, however, heat source 226 is thermally coupled to n+ type  
25 doped silicon regions 624 and 622 that do not form part of the tipped structure 650 rather than to regions that do form part of the tipped structure as do regions 224 and 222 do in **Figure 2**. N+ type doped silicon regions 624 and 622 do still perform the electrical isolation  
30 function performed by regions 224 and 222 in **Figure 2**.

Docket No. AUS9-2000-0414-US1

Several methods may be utilized to form the all metal cones as depicted in **Figure 6**. For example, with reference now to **Figure 7**, a cross-sectional view of a sacrificial silicon template that may be used for forming all metal tips is depicted in accordance with the present invention. After the sacrificial silicon template 702 has been constructed having conical pits, a layer of metal may be deposited over the template 702 to produce all metal cones 704. All metal cones 704 may then be used in thermoelectric cooler 600.

With reference now to **Figure 8**, a flowchart illustrating an exemplary method of producing all metal cones using a silicon sacrificial template is depicted in accordance with the present invention. To begin, conical pits are fabricated by anisotropic etching of silicon to create a mold (step 802). This may be done by a combination of KOH etching, oxidation, and/or focused ion-beam etching. Such techniques of fabricating a silicon cone are well known in the art.

The silicon sacrificial template is then coated with a thin sputtered layer of seed metal, such as, for example, titanium or platinum (step 804). Titanium is preferable since platinum forms slightly more rounded tips than titanium, which is very conforming to the conical pits. Next, copper is electrochemically deposited to fill the valleys (conical pits) in the sacrificial silicon template. (step 806). The top surface of the copper is then planarized (step 808). Methods of planarizing a layer of metal are well known in the art. The silicon oxide ( $\text{SiO}_2$ ) substrate is then removed by selective etching methods well known in the

Docket No. AUS9-2000-0414-US1

art (step 810). The all metal cones produced in this manner may then be covered with a coat of another metal, such as, for example, nickel or titanium and then with an ultra-thin layer of thermoelectric material. The nickel  
5 or titanium overcoat aids in electrodeposition of the thermoelectric material overcoat.

One advantage to this method of producing all metal cones is that the mold that is produced is reusable. The mold may be reused up to around 10 times before the mold  
10 degrades and becomes unusable. Forming a template in this manner is very well controlled and produces very uniform all metal conical tips since silicon etching is very predictable and can calculate slopes of the pits and sharpness of the cones produced to a very few nanometers.

15 Other methods of forming all metal cones may be used as well. For example, with reference now to **Figure 9**, a cross sectional view of all metal cones 902 formed using patterned photoresist is depicted in accordance with the present invention. In this method, a layer of metal is  
20 formed over the bottom portions of a partially fabricated thermoelectric cooler. A patterned photoresist 904-908 is then used to fashion all metal cones 902 with a direct electrochemical etching method.

With reference now to **Figure 10**, a flowchart  
25 illustrating an exemplary method of forming all metal cones using photoresist is depicted in accordance with the present invention. To begin, small sections of photoresist are patterned over a metal layer, such as copper, of a partially fabricated thermoelectric cooler,  
30 such as thermoelectric cooler 600, in **Figure 6** (step 1002). The photoresist may be patterned in an array of

Docket No. AUS9-2000-0414-US1

sections having photoresist wherein each area of photoresist within the array corresponds to areas in which tips to the all metal cones are desired to be formed. The metal is then directly etched electrochemically (step 5 1004) to produce cones 902 as depicted in Figure 9. The photoresist is then removed and the tips of the all metal cones may then be coated with another metal, such as, for example, nickel (step 1006). The second metal coating over the all metal cones may then be coated with an 10 ultra-thin layer of thermoelectric material (step 1008). Thus, all metal cones with a thermoelectric layer on the tips may be formed which may used in a thermoelectric device, such as, for example, thermoelectric cooler 600. The all metal conical points produced in this manner are 15 not as uniform as those produced using the method illustrated in Figure 8. However, this method currently is cheaper and therefore, if cost is an important factor, may be a more desirable method.

The depicted methods of fabricating all metal cones 20 are merely examples. Other methods may be used as well to fabricate all metal cones for use with thermoelectric coolers. Furthermore, other types of metals may be used for the all metal cone other than copper.

With reference now to Figure 11, a cross-sectional 25 view of a thermoelectric cooler with enhanced structural interfaces in which the thermoelectric material rather than the metal conducting layer is formed into tips at the interface is depicted in accordance with the present invention. Thermoelectric cooler 1100 includes a cold 30 plate 1116 and a hot plate 1102, wherein the cold plate is in thermal contact with the substance that is to be

Docket No. AUS9-2000-0414-US1

cooled. Thermal conductors 1114 and 1118 provide a thermal couple between electrical conducting plates 1112 and 1120 respectively. Thermal conductors 1114 and 1118 are constructed of heavily n doped (n+) semiconducting material that provides electrical isolation between cold plate 1116 and conductors 1112 and 1120 by forming reverse biased diodes with the p- material of the cold plate 1116. Thus, heat is transferred from the cold plate 1116 through conductors 1112 and 1120 and eventually to hot plate 1102 from which it can be dissipated without allowing an electrical coupling between the thermoelectric cooler 1100 and the substance that is to be cooled. Similarly, thermal conductor 1104 provides a thermal connection between electrical conducting plate 1108 and hot plate 1102, while maintaining electrical isolation between the hot plate and electrical conducting plate 1108 by forming a reverse biased diode with the hot plate 1102 p- doped semiconducting material as discussed above. Thermal conductors 1104 and 1106 are also an n+ type doped semiconducting material. Electrical conducting plates 1108, 1112, and 1120 are constructed from platinum (Pt) in this embodiment. However, other materials that are both electrically conducting and thermally conducting may be utilized as well. Also, it should be mentioned that the areas surrounding tips 1130-1140 and between tips 1130-1140 and thermoelectric materials 1122 and 1110 should be evacuated to produce a vacuum or should be hermetically sealed with a gas, such as, for example, dry nitrogen.

Docket No. AUS9-2000-0414-US1

10073695-001100

In this embodiment, rather than providing contact between the thermoelements and the heat source (cold end) metal electrode (conductor) through an array of points in the metal electrode as in **Figures 2** and **6**, the array of points of contact between the thermoelement and the metal electrode is provided by an array of points **1130-1140** in the thermoelements **1124** and **1126**. In the embodiments described above with reference to **Figures 2** and **6**, the metal electrode at the cold end was formed over silicon tips or alternatively metal patterns were directly etched to form all-metal tips. However, these methods required thermoelectric materials to be deposited over the cold and the hot electrodes by electrochemical methods. The electrodeposited materials tend to be polycrystalline and do not have ultra-planar surfaces. Also, the surface thermoelectric properties may or may not be superior to single crystalline thermoelectric materials. Annealing improves the thermoelectric properties of the polycrystalline materials, but surface smoothness below 100nm roughness levels remains a problem. The tips **1130-1140** of the present embodiment may be formed from single crystal or polycrystal thermoelectric materials by electrochemical etching.

In one embodiment, thermoelement **1124** is comprised of a super lattice of single crystalline  $\text{Bi}_2\text{Te}_3/\text{Sb}_2\text{Te}_3$  and  $\text{Bi}_{0.5}\text{Sb}_{1.5}\text{Te}_3$  and thermoelement **1126** is formed of a super lattice of single crystalline  $\text{Bi}_2\text{Te}_3/\text{Bi}_2\text{Se}_3$  and  $\text{Bi}_2\text{Te}_{2.0}\text{Se}_{0.1}$ . Electrically conducting plate **1120** is coated with a thin layer **1122** of the same thermoelectric material as is the material of the tips **1130-1134** that are nearest thin layer **1120**. Electrically conducting plate **1112** is coated

Docket No. AUS9-2000-0414-US1

with a thin layer 1110 of the same thermoelectric material as is the material of the tips 1136-1140 that are nearest thin layer 1112.

With reference now to **Figure 12**, a flowchart illustrating an exemplary method of fabricating a thermoelectric cooler, such as, for example, thermoelectric cooler 1100 in **Figure 11**, is depicted in accordance with the present invention. Optimized single crystal material are first bonded to metal electrodes by conventional means or metal electrodes are deposited onto single crystal materials to form the electrode connection pattern (step 1202). The other side of the thermoelectric material 1314 is then patterned (step 1204) by photoresist 1302-1306 as depicted in **Figure 13** and metal electrodes are used in an electrochemical bath as an anode to electrochemically etch the surface (step 1206). The tips 1308-1312 as depicted in **Figure 13** are formed by controlling and stopping the etching process at appropriate times.

A second single crystal substrate is thinned by chemical-mechanical polishing and then electrochemically etching the entire substrate to nanometer films (step 1210). The second substrate with the ultra-thin substrate forms the cold end and the two substrates (the one with the ultra-thin thermoelectric material and the other with the thermoelectric tips) are clamped together with pressure (step 1212). This structure retains high crystallinity in all regions other than the interface at the tips. Also, the same method can be used to fabricate polycrystalline structures rather than single crystalline structures.

Docket No. AUS9-2000-0414-US1

With reference now to **Figure 14**, a diagram showing a cold point tip above a surface for use in a thermoelectric cooler illustrating the positioning of the tip relative to the surface is depicted in accordance with the present invention. Although the tips, whether created in as all-metal or metal coated tips or as thermoelectric tips have been described thus far as being in contact with the surface opposite the tips. However, although the tips may be in contact with the opposing surface, it is preferable that the tips be near the opposing surface without touching the surface as depicted in **Figure 14**. The tip **1402** in **Figure 14** is situated near the opposing surface **1404** but is not in physical contact with the opposing surface. Preferably, the tip **1402** should be a distance  $d$  on the order of 5 nanometers or less from the opposing surface **1404**. In practice, with a thermoelectric cooler containing thousands of tips, some of the tips may be in contact with the opposing surface while others are not in contact due to the deviations from a perfect plane of the opposing surface.

By removing the tips from contact with the opposing surface, the amount of thermal conductivity between the cold plate and the hot plate of a thermoelectric cooler may be reduced. Electrical conductivity is maintained, however, due to tunneling of electrons between the tips and the opposing surface.

The tips of the present invention have also been described and depicted primarily as perfectly pointed tips. However, as illustrated in **Figur 14**, the tips in practice will typically have a slightly more rounded tip as is the case with tip **1402**. However, the closer to

Docket No. AUS9-2000-0414-US1

perfectly pointed the tip is, the fewer number of superlattices needed to achieve the temperature gradient between the cool temperature of the tip and the hot temperature of the hot plate.

5            Preferably, the radius of curvature  $r_0$  of the curved end of the tip 1402 is on the order of a few tens of nanometers. The temperature difference between adjacent areas of the thermoelectric material below surface 1404 approaches zero over a distance of two (2) to three (3) times the radius of curvature  $r_0$  of the end of tip 1402. Therefore, only a few layers of the super lattice 1406-1414 are necessary. Thus, a superlattice material opposite the tips is feasible when the electrical contact between the hot and cold plates is made using the tips of the present invention. This is in contrast to the prior art in which to use a superlattice structure without tips, a superlattice of 10000 or more layers was needed to have a sufficient thickness in which to allow the temperature gradient to approach zero. Such a number of layers was impractical, but using only 5 or 6 layers as in the present invention is much more practical.

Although the present invention has been described primarily with reference to a thermoelectric cooling device (or Peltier device) with tipped interfaces used for cooling, it will be recognized by those skilled in the art that the present invention may be utilized for generation of electricity as well. It is well recognized by those skilled in the art that thermoelectric devices can be used either in the Peltier mode (as described above) for refrigeration or in the Seebeck mode for electrical power generation. Referring now to Figure 15,

Docket No. AUS9-2000-0414-US1

a schematic diagram of a thermoelectric power generator is depicted. For ease of understanding and explanation of thermoelectric power generation, a thermoelectric power generator according to the prior art is depicted  
5 rather than a thermoelectric power generator utilizing cool point tips of the present invention. However, it should be noted that in one embodiment of a thermoelectric power generator according to the present invention, the thermoelements 1506 and 1504 are replaced  
10 cool point tips, as for example, any of the cool point tip embodiments as described in greater detail above.

In a thermoelectric power generator 1500, rather than running current through the thermoelectric device from a power source 102 as indicated in **Figure 1**, a  
15 temperature differential,  $T_H - T_L$ , is created across the thermoelectric device 1500. Such temperature differential,  $T_H - T_L$ , induces a current flow,  $I$ , as indicated in **Figure 15** through a resistive load element 1502. This is the opposite mode of operation from the  
20 mode of operation described in **Figure 1**

Therefore, other than replacing a power source 102 with a resistor 1502 and maintaining heat elements 1512 and 1516 and constant temperatures  $T_H$  and  $T_L$  respectively with heat sources  $Q_H$  and  $Q_L$  respectively, thermoelectric  
25 device 1500 is identical in components to thermoelectric device 102 in **Figure 1**. Thus, thermoelectric cooling device 1500 utilizes p-type semiconductor 1504 and n-type semiconductor 1506 sandwiched between poor electrical  
conductors 1508 that have good heat conducting  
30 properties. Each of elements 1504, 1506, and 1508

Docket No. AUS9-2000-0414-US1

correspond to elements 104, 106, and 108 respectively in Figure 1. Thermoelectric device 1500 also includes electrical conductors 1510 and 1514 corresponding to electrical conductors 110 and 114 in Figure 1. More  
5 information about thermoelectric electric power generation may be found in CRC Handbook of Thermoelectrics, edited by D. M. Rowe, Ph.D., D.Sc., CRC Press, New York, (1995) pp. 479-488 and in Advanced Engineering Thermodynamics, 2nd Edition, by Adiran Bejan,  
10 John Wiley & Sons, Inc., New York (1997), pp. 675-682, both of which are hereby incorporated herein for all purposes.

The present invention has been described primarily with reference to conically shaped tips, however, other  
15 shapes of tips may be utilized as well, such as, for example, pyramidically shaped tips. In fact, the shape of the tip does not need to be symmetric or uniform as long as it provides a discrete set of substantially pointed tips through which electrical conduction between  
20 the two ends of a thermoelectric cooler may be provided. The present invention has applications to use in any small refrigeration application, such as, for example, cooling main frame computers, thermal management of hot chips and RF communication circuits, cooling magnetic  
25 heads for disk drives, automobile refrigeration, and cooling optical and laser devices.

The description of the present invention has been presented for purposes of illustration and description, but is not intended to be exhaustive or limited to the  
30 invention in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in

Docket No. AUS9-2000-0414-US1

the art. The embodiment was chosen and described in order to best explain the principles of the invention, the practical application, and to enable others of ordinary skill in the art to understand the invention for  
5 various embodiments with various modifications as are suited to the particular use contemplated.
